Numerical Solution of Geothermal Heat Exchangers Formulation

MOHAMMED AWWAD ALI AL-DABBAS
Mutah University
Assistant, prof., madabbas@yahoo.com

Abstract
Geothermics has an increasing importance for energy supply worldwide. Hence, there is also an increasing need to model different geothermal scenarios. Depending on the type of problem it may be necessary to take density coupled processes into account. Furthermore, thermal dependence of material properties should be considered. Special problems occur in cases of fracture flow, which can be of high importance with respect to productivity. Finally, the simultaneous modeling of heat and mass transport processes may be necessary. Several simulation codes are available which apply different numerical methods. However, the applicability for complex subsurface geometries reduces the number substantially. We will present modeling approaches with ANSAS. These will include applications for deep geothermics (enhanced geothermal systems), the use of mine-water for heating purposes and the numerically efficient modeling of shallow ground heat exchanger arrays.

Key words: borehole, Geothermics, ground heat exchanger, finite difference,

1 Introduction
In the past, the main driving force for hydrogeologic studies has been the need to assess the water-supply potential of aquifers. During the past 20 years, however, the emphasis has shifted from water-supply problems to water-quality problems. This has driven a need to predict the movement of contaminants through the subsurface environment. One consequence of the change in emphasis has been a shift in perceived priorities for scientific research and data collection. Formerly, the focus was on developing methods to assess and measure the water-yielding properties of high-permeability aquifers. The focus is now largely on transport
and dispersion processes retardation and degradation of chemical contaminants, the effects of heterogeneity on flow paths and travel times, and the ability of low-permeability materials to contain contaminated groundwater (Konikow, 1996).
The past 20 years or so have also seen some major technological breakthroughs in groundwater hydrology. One technological growth area has been in the development and use of deterministic, distributed-parameter, computer simulation models for analysing flow and solute transport in groundwater systems. These developments have somewhat paralleled the development and widespread availability of faster, larger memory, more capable, yet less expensive computer systems. Another major technological growth area has been in the application of isotopic analyses to groundwater hydrology, wherein isotopic measurements are being used to help interpret and define groundwater flow paths, ages, recharge areas, leakage, and interactions with surface water (Konikow, 1996), (Coplen 1993).
Because isotopes move through groundwater systems under the same driving forces and by the same processes as do dissolved chemicals, it is natural that the groundwater flow and solute-transport models applied to groundwater contamination problems be linked to and integrated with isotopic measurements and interpretations. Many previous applications of isotopic analyses to groundwater systems, however, have assumed overly simplified conceptual models for groundwater flow and transport of dissolved chemicals—either plug flow (with piston-like displacement and no mixing) or a well-mixed reservoir (which unrealistically overestimates the mixing effects of dispersion and diffusion). If the interpretations of isotopic analyses are coupled with more realistic conceptual models of flow and transport, then it is anticipated that the synergistic analysis will lead to a more accurate understanding of the hydrogeologic system being studied. Dincer and Davis (1984) provide a review of the application of environmental isotope tracers to modelling in hydrology, and Johnson and DePaolo (1994) provide an example of applying such a coupled approach in their analysis of a proposed high-level radioactive waste repository site (Konikow, 1996) (Dincer and Davis 1984; Johnson and DePaolo 1994).
The purpose of this chapter is to review the state of the art in deterministic modelling of groundwater flow and transport processes for those who might want to merge the interpretation of isotopic analyses with quantitative groundwater model analysis. This chapter is aimed at practitioners and is intended to help define the types of models that are available and how they may be applied to complex field problems. It will discuss the philosophy and theoretical basis of deterministic modelling, the advantages and limitations of models, the use and misuse of models, how to select a model, and how to calibrate a model. However, as this chapter is only a review, it cannot offer comprehensive and in-depth coverage of this very complex topic; but it does guide the reader to references that provide more details. Other recent comprehensive reviews of the theory and practice of deterministic modelling of groundwater processes are provided by

2 Problem Formulations

2.1 MODELS

The word model has so many definitions and is so overused that it is sometimes difficult to discern the meaning of the word (Konikow and Bredehoeft 1992). A model is perhaps most simply defined as a representation of a real system or process. A conceptual model is a hypothesis for how a system or process operates. This hypothesis can be expressed quantitatively as a mathematical model. Mathematical models are abstractions that represent processes as equations, physical properties as constants or coefficients in the equations, and measures of state or potential in the system as variables (Konikow, 1996).

Most groundwater models in use today are deterministic mathematical models. Deterministic models are based on conservation of mass, momentum, and energy and describe cause and effect relations. The underlying assumption is that given a high degree of understanding of the processes by which stresses on a system produce subsequent responses in that system, the system's response to any set of stresses can be predetermined, even if the magnitude of the new stresses falls outside of the range of historically observed stresses (Konikow, 1996).

Deterministic groundwater models generally require the solution of partial differential equations. Exact solutions can often be obtained analytically, but analytical models require that the parameters and boundaries be highly idealised. Some deterministic models treat the properties of porous media as lumped parameters (essentially, as a black box), but this precludes the representation of heterogeneous hydraulic properties in the model. Heterogeneity, or variability in aquifer properties, is characteristic of all geologic systems and is now recognised as playing a key role in influencing groundwater flow and solute transport. Thus, it is often preferable to apply distributed-parameter models, which allow the representation of more realistic distributions of system properties. Numerical methods yield approximate solutions to the governing equation (or equations) through the discretisation of space and time. Within the discretised problem domain, the variable internal properties, boundaries, and stresses of the system are approximated. Deterministic, distributed-parameter, numerical models can relax the rigid idealised conditions of analytical models or lumped-parameter models, and they can therefore be more realistic and flexible for simulating field conditions (if applied properly) (Konikow, 1996).

The number and types of equations to be solved are determined by the concepts of the dominant governing processes. The coefficients of the equations are the parameters that are measures of the properties, boundaries, and stresses of the system; the dependent variables of the equations are the measures of the state of the system and are mathematically determined by the solution of the equations. When a numerical algorithm is implemented in a computer code to solve one or
more partial differential equations, the resulting computer code can be considered a generic model. When the grid dimensions, boundary conditions, and other parameters (such as hydraulic conductivity and storativity), are specified in an application of a generic model to represent a particular geographical area, the resulting computer program is a site-specific model. The ability of generic models to solve the governing equations accurately is typically demonstrated by example applications to simplified problems. This does not guarantee a similar level of accuracy when the model is applied to a complex field problem (Konikow, 1996). If the user of a model is unaware of or ignores the details of the numerical method, including the derivative approximations, the scale of discretisation, and the matrix solution techniques, significant errors can be introduced and remain undetected. For example, if the groundwater flow equation is solved iteratively, but the convergence criterion is relatively too coarse, then the numerical solution may converge, but to a poor solution. The inaccuracy of the solution may or may not be reflected in the mass-balance error. Unrecognized errors in numerical groundwater models are becoming more possible as “user-friendly” graphical interfaces make it easier for models to be used (and to be misused). These interfaces effectively place more “distance” between the modeller and the numerical method that lies at the core of the model (Konikow, 1996).

2.2 FLOW AND TRANSPORT PROCESSES
The process of groundwater flow is generally assumed to be governed by the relations expressed in Darcy's law and the conservation of mass. Darcy's law does have limits on its range of applicability, however, and these limits must be evaluated in any application (Konikow, 1996).

The purpose of a model that simulates solute transport in groundwater is to compute the concentration of a dissolved chemical species in an aquifer at any specified time and place. The theoretical basis for the equation describing solute transport has been well documented in the literature (Bear 1997; Domenico and Schwartz 1998). Reilly et al. (1987) provide a conceptual framework for analyzing and modeling physical solute-transport processes in groundwater (Reilly et al. 1987), (Konikow, 1996). Changes in chemical concentration occur within a dynamic groundwater system primarily due to four distinct processes:

1) advective transport, in which dissolved chemicals are moving with the flowing groundwater;
2) Hydrodynamic dispersion, in which molecular and ionic diffusion and small-scale variations in the flow velocity through the porous media cause the paths of dissolved molecules and ions to diverge or spread from the average direction of groundwater flow
3) Fluid sources, where water of one composition is introduced into and mixed with water of a different composition
4) Reactions, in which some amount of a particular dissolved chemical species may be added to or removed from the groundwater as a result of chemical,
biological, and physical reactions in the water or between the water and the solid aquifer materials or other separate liquid phases.

The subsurface environment constitutes a complex, three-dimensional, heterogeneous hydrogeologic setting. This variability strongly influences groundwater flow and transport, and such a reality can be described accurately only through careful hydrogeologic practice in the field. Regardless of how much data are collected, however, uncertainty always remains about the properties and boundaries of the groundwater system of interest. Stochastic approaches have resulted in many significant advances in characterising subsurface heterogeneity and dealing with uncertainty (Konikow, 1996), (Gelhar 1993).

2.3 GOVERNING EQUATIONS

The development of mathematical equations that describe the groundwater flow and transport processes may be developed from the fundamental principle of conservation of mass of fluid or of solute. Given a representative volume of porous medium, a general equation for conservation of mass for the volume may be expressed as:

\[
\text{(rate of mass inflow)} - \text{(rate of mass outflow)} + \text{(rate of mass production/consumption)} = \text{(rate of mass accumulation)}
\]

This statement of conservation of mass (or continuity equation) may be combined with a mathematical expression of the relevant process to obtain a differential equation describing flow or transport (Konikow, 1996), (Bear 1997; Domenico and Schwartz 1998; Freeze and Cherry 1979).

2.3.1 GROUNDWATER FLOW EQUATION

The rate of flow of water through a porous media is related to the properties of the water, the properties of the porous media, and the gradient of the hydraulic head, as represented by Darcy’s law, which can be written as (Konikow, 1996):

\[
q_i = -k_{ij} \frac{\partial h}{\partial x_j}
\]

where \( q_i \) is the specific discharge, \( LT^{-1} \); \( K_{ij} \) is the hydraulic conductivity of the porous medium (a second-order tensor), \( LT^{-1} \); and \( h \) is the hydraulic head, \( L \).

A general form of the equation describing the transient flow of a compressible fluid in a non-homogeneous anisotropic aquifer may be derived by combining Darcy’s law with the continuity equation. A general groundwater flow equation may be written in Cartesian tensor notation as (Konikow, 1996):

\[
\frac{\partial}{\partial t} \left( k_{ij} \frac{\partial h}{\partial x_i} \right) = S_s \frac{\partial h}{\partial t} + w^*
\]

where \( S_s \) is the specific storage, \( L^{-1} \); \( t \) is time, \( T \); \( w^* \) is the volumetric flux per unit volume (positive for outflow and negative for inflow), \( T^{-1} \); and \( x_i \) are the Cartesian co-ordinates, \( L \). The summation convention of Cartesian tensor analysis
is implied in Eqs.4.2 and 4.3. Eq.4.3 can generally be applied if isothermal conditions prevail, the porous medium only deforms vertically, the volume of individual grains remains constant during deformation, Darcy's law applies (and gradients of hydraulic head are the only driving force), and fluid properties (density and viscosity) are homogeneous and constant. Aquifer properties can vary spatially, and fluid stresses ($W^*$) can vary in space and time (Konikow, 1996).

If the aquifer is relatively thin compared to its lateral extent, it may be appropriate to assume that groundwater flow is areally two-dimensional. This allows the three-dimensional flow equation to be reduced to the case of two-dimensional areal flow, for which several additional simplifications are possible. The advantages of reducing the dimensionality of the equation include less stringent data requirements, smaller computer memory requirements, and shorter computer execution times to achieve numerical solutions (Konikow, 1996).

An expression similar to Eq.4.3 may be derived for the two-dimensional a real flow of a homogeneous fluid in a confined aquifer and written as:

$$\frac{\partial}{\partial x_i} \left( T_{ij} \frac{\partial h}{\partial x_j} \right) = S \frac{\partial h}{\partial t} + w$$

where $T_{ij}$ is the transmissivity, $L^2T^{-1}$; and $T_{ij} = K_{ij} b$; $b$ is the saturated thickness of the aquifer, $L$; $S$ is the storage coefficient (dimensionless); and $W = W^*b$ is the volume flux per unit area, $LT^{-1}$.

When Equation is applied to an unconfined (water-table) aquifer system, it must be assumed that flow is horizontal and equipotential lines are vertical, that the horizontal hydraulic gradient equals the slope of the water table, and that the storage coefficient is equal to the specific yield ($S_y$) (Anderson and Woessner 1992). Note that in an unconfined system, the saturated thickness changes as the water-table elevation (or head) changes. Thus, the transmissivity also can change over space and time (i.e. $T_{ij} = K_{ij} b$; $b(x,y,t) = h_b$, and $h_b$ is the elevation of the bottom of the aquifer) (Konikow, 1996).

In some field situations, fluid properties such as density and viscosity may vary significantly in space or time. This may occur where water temperature or dissolved-solids concentration changes significantly. When the water properties are heterogeneous and (or) transient, the relations among water levels, hydraulic heads, fluid pressures, and flow velocities are neither simple nor straightforward. In such cases, the flow equation is written and solved in terms of fluid pressures, fluid densities, and the intrinsic permeability of the porous media (Konikow and Grove 1977).

### 2.3.2 Geothermal energy

Geothermal energy is the heat contained in the solid earth and its internal fluids. This sets it apart from other terrestrial energy sources. It represents a vast supply
which has only started to be tapped by mankind for space heating, process heat and generation of electric power. (Clauser, 2006)
The efficient use of this natural resource can be optimized by applying numerical heat-transport models. In the following we will give an introduction on the modeling of different geothermal utilization scenarios using ANSAS, (Konikow, 1996) (Diersch, 2005; Trefry & Muffels, 2007).

2.3.3 Coupled modeling of flow and heat transport
The computation of heat transport within a porous medium requires the solution of a set of balance equations. For comprehensibility only flow in a saturated medium is discussed. Of course, advanced heat and groundwater modeling codes are also able to compute unsaturated flow, fracture flow and other special processes.
The mass conservation equation of a fluid in a saturated porous medium is given by (Diersch, 2005)

\[ S_0 \frac{\partial}{\partial t} \left( k (\nabla h + \chi^e) \right) + Q \]

where \( S_0 \) is the specific storage due to fluid and medium compressibility \( (m^{-1}) \), \( h \) is the hydraulic head \( (m) \), \( t \) is time \( (s) \), \( \chi^e \) the buoyancy coefficient and \( e \) is the gravitational unit vector. \( Q \) corresponds to sources and sinks.

\[ K \equiv \frac{k \rho^f g}{\mu^f} \]

\( \mu^f \) is the dynamic fluid viscosity.
The Darcy velocity \( q \) is given by

\[ q = -k (\nabla h + \chi^e) \]

The heat transport with conductive and advective parts reads

\[ (\rho c)^s \frac{\partial T}{\partial t} = \nabla \cdot \left( \lambda \nabla T - \rho^f c^f q T \right) + H \]

where \( T \) is the temperature \( (K) \), \( c \) is the specific heat and \( \lambda \) is the heat conductivity. \( (\rho c)^s \) is bulk volumetric heat capacity. \( H \) refers to sources and sinks.

3 Geothermics
Geothermal installations are generally distinguished between shallow (using boreholes with depths up to 400 m) and deep geothermics. The latter is sometimes defined by its direct usability, i.e. that it is not necessary to use heat exchangers (A. Renz., 2009).
3.1 Shallow geothermics
Shallow geothermics is mostly used via borehole heat exchangers, which utilize the temperature difference between the atmosphere and ground. Different technologies exist, e.g., U-shape heat pipe, double U-shape heat pipe, coaxial heat pipes and grounding stakes. Such ground heat exchangers form a vertical borehole system, where a refrigerant circulates in closed pipes exchanging heat with the surrounding aquifer driven alone by thermal conductivity (closed loop system). Unlike those closed systems a combination of extraction and injection wells can be used in an open system, see Figure 2. A procedure of special interest refers to the combined use of solar energy and geothermics, i.e., the storage of solar energy in the ground. For instance, in order to give expertise on environmental matters it may be necessary to model the impact of ground heat exchangers on the subsurface temperature. In the following some introductive modeling scenarios are summarized (A. Renz., 2009).

3.2 Open loop
In Figure 3 modeling results for combining an extraction and injection well are shown. At the injection well a special module, which has been programmed for this purpose, adds a variable temperature difference on the temperature of the extracted water. Due to groundwater flow, the temperature at the extraction well increases in time (A. Renz., 2009).

3.3 Geothermal heat pump systems
Geothermal heat pump systems, employing the ground as media of heat exchanger with the surrounding through ground heat exchangers, offer higher energy efficiency and lesser environmental impact than air-cooled systems. Vertical ground heat exchangers (with U tubes installed inside boreholes) are most common, requiring lesser land field. Fig. 1 shows the general arrangement of a borehole ground heat exchanger and pipe connection in a borefield. However, drilling of deep boreholes involves a high initial cost, which hinders the application of such systems. To reduce cost, precise system design becomes very important (Lee, C.K., 2008).
4 Numerical formulation (Lee, C.K., 2008)

In developing the numerical scheme, the following assumptions were made:

- The ground was homogeneous;
- The thermal properties of all the arterials remain constant within the temperature range investigated;
- The boreholes and the ground had no contact resistance;
- The ground temperature remained unchanged at the to surface and at a distance far below the boreholes and away in the transverse directions;
- Quasi-steady state was maintained inside the boreholes;
- Fluid flow rate in each tube of boreholes was the same;
- Fluid flow rate in each borehole was the same.

4.1 Heat transfer around borehole (Lee, C.K., 2008)

Figure 1 General arrangement of borehole ground heat exchanger

Figure 2: Grid scheme for ground around borehole
Fig. 2 shows the grid scheme used for the ground around borehole. The implicit difference equation with regular grids can be obtained by direct discretization of the governing differential equation for conductive heat transferring the ground as Field ((Lee, C.K., 2008)

\[
\frac{T_{i,j,m}^{n+1} - T_{i,j,m}^n}{\Delta t} = a_g \left( \frac{T_{i,j+1,m}^{n+1} - 2T_{i,j,m}^{n+1} + T_{i,j-1,m}^{n+1}}{(\Delta x)^2} + \frac{T_{i,j+1,m}^{n+1} - 2T_{i,j,m}^{n+1} + T_{i,j-1,m}^{n+1}}{(\Delta y)^2} \right)
\]

Eq. (1) can be re-written in energy balance form with irregular grids as

\[
\frac{T_{i,j,m}^{n+1} - T_{i,j,m}^n}{\Delta t} = \left( \frac{q_{x+} + q_{x-} + q_{y+} + q_{y-} + q_{z+} + q_{z-}}{\rho c_g \Delta x \Delta y \Delta z_i} \right)
\]

where

\[
q_{x+} = k_g \Delta y_m \Delta z_i \frac{T_{i,j+1,m}^{n+1} - T_{i,j,m}^{n+1}}{dx_j}
\]

\[
q_{x-} = k_g \Delta y_m \Delta z_i \frac{T_{i,j-1,m}^{n+1} - T_{i,j,m}^{n+1}}{dx_{j-1}}
\]

\[
q_{y+} = k_g \Delta x_j \Delta z_i \frac{T_{i,j+1,m}^{n+1} - T_{i,j,m}^{n+1}}{dy_m}
\]

\[
q_{y-} = k_g \Delta x_j \Delta z_i \frac{T_{i,j-1,m}^{n+1} - T_{i,j,m}^{n+1}}{dy_{m-1}}
\]

\[
q_{z+} = k_g \Delta y_m \Delta x_j \frac{T_{i+1,j,m}^{n+1} - T_{i,j,m}^{n+1}}{dz_i}
\]

\[
q_{z-} = k_g \Delta y_m \Delta x_j \frac{T_{i-1,j,m}^{n+1} - T_{i,j,m}^{n+1}}{dz_{i-1}}
\]

The source term \( q_s \) equals one-quarter of the borehole load multiplied by a load factor \( f \) (value to be determined in a later section) at each corner point of the borehole and zero elsewhere.

4.2 Heat transfer inside borehole (Lee, C.K., 2008)
Fig. 3 shows the grid scheme used for the boreholes. With fluid flowing in the tubes, the fluid temperatures along the tubes are strongly coupled. Hence, all grid fluid temperatures have to be solved simultaneously. On the other hand, with no fluid flowing in the tubes, the fluid temperatures along the tubes (not within the same control volume) were weakly coupled (assuming conduction along the tubes to be small compared with that in the transverse direction). Hence, the numerical formulation is different. The borehole temperature $T_{bi}$ and loading $q_{bi}$ are defined at mid level of the control volume while ground temperatures are defined at the grid points. Hence, eight round temperatures are required to calculate one borehole temperature, and that the source term $q_s$ at particular ground grid point on the borehole surface should be determined from the borehole loading above and below the ground grid point.

4.3 Flow process

For a borehole containing $N$ tubes and assuming steady state conditions,

$$ (-1)^{m_1} M_C \frac{dTf1_u}{dz} = \sum_{v=1}^{u-1} \frac{Tf1_u - Tf1_v}{R_{uv}} + \frac{Tf1_u - Th}{R_{uv}} + \sum_{v=u+1}^{N} \frac{Tf1_u - Tf1_v}{R_{uv}} $$

Where $m_1$ is 1 for downward flowing tubes and 2 for upward flowing tubes. By replacing the fluid temperatures with the grid point temperatures, Eq. (3) can be re-written as
Eq. (4) represents $N_z$ nzbore coupled equations in $N_z$ nzbore variables $T_{f,i,u}$ by writing Eq. (4) consecutively for $i=1$ to $nzbore$ and $u=1$ to $N$, which are solved iteratively based on prescribed fluid inlet temperature, pipe connection configuration and borehole temperatures. The borehole loading is then calculated as

$$q_b = (-1)^{n_1} M_c \frac{d}{d z_i} \left( T_{f,i+1,u} - T_{f,i,u} \right)$$

No flow process with no fluid flowing in the tubes, there is no directional dependence, and the governing differential equation (assuming heat conduction in transverse direction only)

$$-\pi r_i^2 \rho \frac{2}{C_f} \frac{d T_f l_{u,i,u}}{d t} = \sum_{v=1}^{u-1} \frac{T_f l_{v+1,u} - T_f l_{v,u}}{R_n f_{avuv}} + \frac{T_f l_{v,u} - T_{b,v}}{R_n f_{avuv}}$$

becomes

$$-\pi r_i^2 \rho \frac{2}{C_f} \frac{d T_f l_{u,i,u}}{d t} = \sum_{v=1}^{u-1} \frac{T_f l_{v+1,u} - T_f l_{v,u}}{R_n f_{avuv}} + \frac{T_f l_{v,u} - T_{b,v}}{R_n f_{avuv}}$$

which can be discretized as

$$-\pi r_i^2 \rho \frac{2}{C_f} \frac{d T_f l_{u,i,u}}{d t} = \sum_{v=1}^{u-1} \frac{T_f l_{v+1,u} - T_f l_{v,u}}{R_n f_{avuv}} + \frac{T_f l_{v,u} - T_{b,v}}{R_n f_{avuv}}$$

To solve $T_f l_{u,i,u}^{n+1}$, Eq. (7) is re-written as

$$c_f T_f l_{u,i,u}^{n+1} + \frac{T_{b,v}}{R_n f_{uv}} = \sum_{v=1}^{u-1} \frac{T_f l_{v+1,u}^{n+1} - T_f l_{v,u}^{n+1}}{R_n f_{avuv}} + \frac{T_f l_{v,u}^{n+1} - T_{b,v}}{R_n f_{avuv}} + \sum_{v=1}^{u-1} \frac{T_f l_{v+1,u}^{n+1} - T_f l_{v,u}^{n+1}}{R_n f_{avuv}}$$

$$+ \sum_{v=1}^{u-1} \frac{T_f l_{v,u}^{n+1} - T_{b,v}}{R_n f_{avuv}}$$

$$-\pi r_i^2 \rho \frac{2}{C_f} \frac{d T_f l_{u,i,u}}{d t} = \sum_{v=1}^{u-1} \frac{T_f l_{v+1,u} - T_f l_{v,u}}{R_n f_{avuv}} + \frac{T_f l_{v,u} - T_{b,v}}{R_n f_{avuv}}$$

Where $C_f = \frac{\pi r_i^2 \rho \frac{2}{C_f}}{\Delta t}$

Eq. (8) can be expressed in matrix form as
\[
\begin{bmatrix}
C_f T f l_{i,u}^n + T b_i^n \\
\Delta R n f_{uv}^n
\end{bmatrix}
= \begin{bmatrix}
R n f
\end{bmatrix}
\begin{bmatrix}
T f l_{i,v}^{n+1}
\end{bmatrix}
\]

Where
\[
\begin{bmatrix}
R n f
\end{bmatrix}
= \frac{1}{R n f}, \text{ for } u \neq v
\]

\[
\begin{bmatrix}
R n f
\end{bmatrix}
= \sum_{r=1}^{N} \frac{1}{R n f} + C f
\]

Hence
\[
\begin{bmatrix}
R n f
\end{bmatrix}^{-1}
\begin{bmatrix}
C_f T f l_{i,u}^n + T b_i^n \\
\Delta R n f_{uv}^n
\end{bmatrix}
= \begin{bmatrix}
T f l_{i,v}^{n+1}
\end{bmatrix}
\]

4.4 Borefield performance formulation (Lee, C.K., 2008)

The inlet fluid temperature can be calculated as
\[
T_{in}^{n+1} = T_{out}^n + \frac{Q}{M_{total} C_f}
\]

The load transferred to the borefield is then evaluated as
\[
Q_{doc} = M_{total} C_f \left( T_{in}^{n+1} - T_{out}^{n+1} \right)
\]

Thermal resistance for the entire borefield can be defined as
\[
R_{b_{bf}} = \frac{N_{bore} H \left( T_{in} + T_{out} - 2 \bar{T} b \right)}{2 Q_{bf}}
\]

5 Results and discussion

5.1 Temperature and loading profile along borehole

It was found that neither the temperature nor the loading was constant along the borehole. The borehole temperature reached a maximum near the top part of the borehole rather than near the middle level of borehole if a finite line source model was used. The bore hole loading decreased with depth up to the bottom end of borehole. This could be explained by considering the fact that the mean fluid temperature inside the borehole decreased with depth (see Fig. 4). Hence, near the top of borehole where the borehole temperature increased with depth, the bore hole loading decreased (due to reduced temperature difference between fluid and borehole). The situation changed only beyond the depth where the borehole
temperature decreased with depth at a higher rate than the mean fluid temperature (near the lower part of borehole). Basically, the borehole temperature and loading profiles changed very mildly with time. Indeed, very similar profiles were obtained when using cylindrical coordinate system for a single borehole.

5.2 Ground temperature profiles around borehole

Figs. 5 show the ground temperature profiles at various distances from the borehole after 1, 10 year using ANSAS programm. The temperature profiles at the borehole were different from those away from borehole. At distance far from the borehole, the depth of maximum temperature shifted to mid-level of the borehole. This meant that the thermal interference effect between two boreholes in a bore field would depend both on the borehole spacing and depth. To apply the method of superposition to estimate the performance of a bore field, individual finite difference scheme would be needed for each borehole for precise simulation. A simpler way was to discretize the entire bore field, and perform the simulation for all bore holes simultaneously. This was easily achieved when using rectangular coordinate system by expanding the original grid system in transverse directions to cover the entire bore.

![Comparison of fluid temperature rise and borehole temperature rise after 1 year using ANSAS programm.](image-url)
Fig. 5. Ground temperature profiles at various distances from borehole after 10 years using ANSAS programm.

6 Conclusions
A numerical model was developed to predict heat extraction and injection rates of a ground heat exchanger.
- it is based on simulation code for the analysis of underground heat and water movement, in which circulatory water model in the heat exchanger and the ground surface heat flux model are incorporated.
- an estimation method for the soil thermal properties based on a ground investigation and theoretical formulas was proposed.

<td>ground grid spacing in (x) direction ((\text{m}))</td>
</tr>
<tr>
<td>( N_{\text{bore}} )</td>
<td>number of boreholes in a borefield</td>
</tr>
<tr>
<td>( d_y )</td>
<td>ground grid spacing in (y) direction ((\text{m}))</td>
</tr>
<tr>
<td>( d_z )</td>
<td>ground grid spacing in (z) direction ((\text{m}))</td>
</tr>
<tr>
<td>( p_r )</td>
<td>Prandtl number</td>
</tr>
<tr>
<td>( Q )</td>
<td>applied load to a borefield ((\text{W}))</td>
</tr>
<tr>
<td>( Q_{bf} )</td>
<td>load transferred from borefield to ground ((\text{W}))</td>
</tr>
<tr>
<td>( q_k )</td>
<td>borehole loading per unit length ((\text{W/m}))</td>
</tr>
<tr>
<td>( R_{av} )</td>
<td>thermal interference coefficient between tube (u) and (v) according to Eq. (A.1) ((\text{m}_k/\text{W}))</td>
</tr>
<tr>
<td>( R_{av} )</td>
<td>element of inverse matrix of ( R_{av} ) between tube (u) and (v) ((\text{m}_k/\text{W}))</td>
</tr>
<tr>
<td>( q_s )</td>
<td>source term in the finite difference equation ((\text{W}))</td>
</tr>
<tr>
<td>( R_{UV} )</td>
<td>thermal interference coefficient between tube (u) and (v) according to Eq. (3) ((\text{m}_k/\text{W}))</td>
</tr>
<tr>
<td>( q_t )</td>
<td>tube loading per unit length inside borehole ((\text{W/m}))</td>
</tr>
<tr>
<td>( R_{bf} )</td>
<td>thermal resistance of entire borefield ((\text{m}_k/\text{W}))</td>
</tr>
<tr>
<td>( q_{sv} )</td>
<td>heat load into control volume of ground</td>
</tr>
<tr>
<td>( Re )</td>
<td>Reynolds number</td>

<tr>
<td>------</td>
<td>-------------</td>
</tr>
<tr>
<td>$q_x$</td>
<td>heat load into control volume of ground from downstream x direction (W)</td>
</tr>
<tr>
<td>$R_{nfuv}$</td>
<td>thermal interference matrix element between tube u and v according to Eq. (9) at no fluid flow</td>
</tr>
<tr>
<td>$q_y$</td>
<td>heat load into control volume of ground from downstream y direction (W)</td>
</tr>
<tr>
<td>$R_{nfuvD}$</td>
<td>thermal interference coefficient between tube u and v according to Eq. (6) at no fluid flow</td>
</tr>
<tr>
<td>$R_b$</td>
<td>thermal resistance between fluid and grouting inside borehole ($m_k/W$)</td>
</tr>
<tr>
<td>$r_{max}$</td>
<td>margin from borefield boundary beyond which the ground temperature was assumed unchanged (m)</td>
</tr>
<tr>
<td>$T_b$</td>
<td>Borehole temperature (K)</td>
</tr>
<tr>
<td>$R_{pi}$</td>
<td>inner radius of tube (m)</td>
</tr>
<tr>
<td>$T_{fi}$</td>
<td>fluid temperature at centre of control volume inside borehole (K)</td>
</tr>
<tr>
<td>$R_{po}$</td>
<td>outer radius of tube (m)</td>
</tr>
<tr>
<td>Tout</td>
<td>fluid temperature leaving a borefield (K)</td>
</tr>
<tr>
<td>$T$</td>
<td>ground temperature (K)</td>
</tr>
<tr>
<td>$t_{max}$</td>
<td>maximum time encountered in the analysis (s)</td>
</tr>
